# ALGORITHMS FOR CHALLENGING MOTIF PROBLEMS* 

HENRY C.M. LEUNG AND FRANCIS Y.L. CHIN ${ }^{\dagger}$<br>Department of Computer Science<br>The University of Hong Kong<br>Pokfulam, Hong Kong

#### Abstract

Pevzner and Sze [19] have introduced the Planted (l,d)-Motif Problem to find similar patterns (motifs) in sequences which represent the promoter regions of co-regulated genes, where $l$ is the length of the motif and $d$ is the maximum Hamming distance around the similar patterns. Many algorithms have been developed to solve this motif problem. However, these algorithms either have long running times or do not guarantee the motif can be found. In this paper, we introduce new algorithms to solve this motif problem. Our algorithms can find motifs in reasonable time for not only the challenging $(9,2)$, $(11,3)$, $(15,5)$-motif problems but for even longer motifs, say $(20,7)$, $(30,11)$ and $(40,15)$, which have never been seriously attempted by other researchers because of large time and space requirements. Besides, our algorithms can be extended to find more complicated motifs structure called cis-regulatory modules (CRM).

## 1 Introduction

Understanding the gene regulatory network, i.e. how genes cooperate to perform functions, is an important problem in Bioinformatics. An important subproblem is to finding motifs for co-regulatory genes.

In order to start the gene expression process, a molecule called the transcription factor will bind to a short substring in the promoter region of the gene. We call this substring a binding site of the transcription factor. A transcription factor can bind to several binding sites in the promoter regions of different genes to make these genes coregulating, and such binding sites should have common patterns. The motif discovering problem is to find the common patterns, or motifs.

Many algorithms [1-3,7-12,14-15,17-20,22-23,25] have been introduced to solve this problem based on different assumptions. Pevzner and Sze [19] define a very precise version of this motif discovery problem which has also been considered in [3,17,20].

Planted ( $\boldsymbol{l , d}$ )-Motif Problem: Suppose there is a fixed but unknown nucleotide sequence $M$ (the motif) of length $l$. Given $t$ length- $n$ nucleotide sequences, and each sequence contains a planted variant of $M$, we want to determine $M$ without knowing the positions of the planted variants. A variant is a substring derivable from $M$ with at most $d$ point substitutions.

[^0]Buhler and Tompa [3] had studied the limitation of this model. They found that when $l, t$ and $n$ are fixed, $d$ must not be larger than some threshold. Otherwise, there are many random patterns (sequences) $P$ such that each input sequence contains a variant of $P$. No algorithm can distinguish the motif $M$ from these random patterns $P$ and therefore it is very unlikely that the motif can be found. They determined the threshold by considering the expected number $\mathrm{E}(l, d)$ of random patterns $P$ with at least one variant in each sequence using the following equation.

$$
E(l, d)=4^{l}\left[1-\left(1-p_{d}\right)^{n-l+1}\right]^{t}
$$

where $p_{d}=\sum_{i=0}^{d} C_{i}^{l}(3 / 4)^{i}(1 / 4)^{l-i}$ is the probability that the Hamming distance between a length- $l$ pattern $P$ and a randomly generated length- $l$ string is less than or equal to $d$. Theoretically, when $\mathrm{E}(l, d)$ is large, no algorithm can find the motif $M$. They further introduced some "challenging" problems, e.g. (9,2), (11,3), (15,5)-motif problems, for $t=$ 20 and $n=600$, in which $\mathrm{E}(l, d)$ are slightly larger than 1 . Many algorithms cannot solve these challenging problems.

The algorithms that have been introduced to solve this problem can be classified into three categories: brute-force, clique search and heuristic search.

Brute-force algorithms [2,9,18,22-23,25] try to test all $4^{l}$ possible motifs. Although these algorithms guarantee that the motif can be found, their running times increase exponentially with $l$. Therefore, they are not suitable for finding long motifs.

Algorithms using clique search approach $[17,19]$ construct a $t$-partite graph $G$. Each partite contains $n-l+1$ nodes which represent all length- $l$ substrings in an input sequence. Two nodes in different partites will be joined by an edge if the Hamming distance between the two corresponding length- $l$ substrings is at most $2 d$. The Planted $(l, d)$-Motif Problem is reduced to finding a clique of size $t$ in graph $G$. These algorithms can handle longer motif than the brute-force algorithms can. However, since the number of edges increases with the value of $d$, these algorithms fail when the number of edges in the graph is large, as in the case of the $(9,2),(11,3),(15,5)$-motif problems (The running time can be $\mathrm{O}\left((n t)^{t+2.376}\right)$ in these cases $)$.

Algorithms based on heuristic search [1,3,7-8,10-12] first find out a set of length- $l$ sequences with high probability of being the motif, then refine these sequences by some local searching techniques, e.g., EM-algorithm [1], Gibbs Sampling [11], etc. Although these algorithms may solve the challenging $(9,2),(11,3),(15,5)$-motif problems in practice, there is no guarantee that the motif can be found even when the motif is short.

As far as we know, until now, no known software can find motifs for large $l$ and $d$. Our contribution includes:

1) Waterman et al. [24] designed an algorithm for finding consensus patterns in a set of sequences by enumerating the neighbors (will be discussed in Section 2) of each length- $l$ substring in the input sequences. Their algorithm takes $\mathrm{O}\left(4^{l} n t(3 l)^{d}\right)$ time when applied to solve the Planted $(l, d)$-Motif Problem directly. We have designed a Voting Algorithm based on similar idea as Waterman et al. with time complexity
$O\left(n t(3 l)^{d}\right)$. Since the Voting Algorithm runs faster than the brute-force algorithms, it can handle longer motifs than brute-force algorithms, e.g., the challenging ( 9,2 ), $(11,3)$, $(15,5)$-motif problems. However, when $l>15$, e.g. $(20,7),(30,11)$ and $(40,15)$-motif problem, even the Voting Algorithm will fail because of large time and space requirements.
2) We have designed a Voting Algorithm with projection. Instead of considering all positions, our improved Voting Algorithm considers only $l$ ' of the $l$ positions of the motif. Based on the voting results on these $l$ ' positions, we can with high probability find the motif of length $l$. In fact, the $l$ ' positions can be chosen randomly and the probability of success can be increased tremendously if different sets of positions are tried. Besides choosing the sets of positions at random, we can have a better result if these positions are the complement set of the previous $l$ ' positions.
3) We have extended the Voting algorithm for finding cis-regulatory patterns which run faster than previous algorithms.
Depending on the sizes of $l$ and $d$, the appropriate algorithm should be applied to find the motif. Experiments on simulated data show that the improved Voting Algorithm with projection can find long motifs, e.g., the $(40,15)$-motif problem with over $95 \%$ successful rate. Note that Buhler et al [3] have shown that no algorithms can find the motif when the value of $l$ is small while the value of $d$ is large because there are many random length- $l$ sequences which can be taken as motifs. Examples of unsolvable cases include (9,3), $(11,4),(15,6),(20,8),(30,14)$ and $(40,19)$-motif problems. Thus, our algorithms can solve the Planted $(l, d)$-Motif Problem with almost the maximum solvable $d$ especially for short motif length $l$.

This paper is organized as follows. We describe the Voting Algorithm in Section 2 and the heuristic improvements in Section 3. Experimental results on both real data and simulated data are shown in Section 4. An extension of the Voting Algorithm on cisregulatory patterns is presented in Section 5 followed by a discussion in Section 6.

## 2 Voting Algorithms

In this section, we will describe the basic Voting Algorithm which runs faster than the brute-force algorithms without compromising its effectiveness.

First, we define a length- $l$ sequence $s$ ' to be a $d$-variant (or simply variant) of another length- $l$ sequence $s$ if the Hamming distance between $s$ ' and $s$ is at most $d$. Let $\mathrm{N}(s, d)$ be the set that contains all $d$-variants of a length- $l$ sequence $s$. Note that all planted variants $m_{i}$ of the motif $M$ in the input sequences are in the set $\mathrm{N}(M, d)$. At the same time, $M$ is also in $\mathrm{N}\left(m_{i}, d\right)$ for all planted variants $m_{i}$ of $M$.

Algorithm 1 outlines the procedure for the Basic Voting Algorithm. The idea of the Basic Voting Algorithm is that each length- $l$ substring $\sigma$ in the input sequences gives one vote to all length- $l$ sequences $s$ in $\mathrm{N}(\sigma, d)$, which is recorded in hash table V in Algorithm 1. If each length- $l$ sequence $s$ can get at most one vote from each input sequence, the motif $M$ will get exactly $t$ votes because of the assumption that each input sequence has
exactly one planted variant of $M$. Hash table R in Algorithm 1 is to ensure that each length- $l$ sequence $s$ receives at most one vote from each input sequence.

```
Algorithm 1: Basic Voting Algorithm
1: Create two hash tables V and R and set the value of each entry be 0
    \{Table V keeps the number of votes received by each length- \(l\) sequence \(s\). Each length- \(l\) sequence,
    received \(t\) votes is a candidate for motif. Hash table R ensures that each length- \(l\) sequence receives at most
    one vote from each input sequence. \(\mathrm{S}_{i}[j]\) is the \(j\)-th character in the \(i\)-th input sequence \(\mathrm{S}_{i}\) and \(\mathrm{H}(s)\) is the
    hash value of a length \(-l\) sequence \(s\).\}
    \(C \leftarrow \phi \quad\) \{set of motifs \(\}\)
    for \(i \leftarrow 1\) to \(t\)
        do \(\mathbf{f o r} j \leftarrow 1\) to \(n-l+1\)
            do for each length \(l\) sequence \(s\) in \(\mathrm{N}\left(\mathrm{S}_{i}[j \ldots j+l-1], d\right)\)
                do if \(\mathrm{R}[\mathrm{H}(\mathrm{s})]<>\mathrm{i}\)
                then \(\mathrm{V}[\mathrm{H}(s)] \leftarrow \mathrm{V}[\mathrm{H}(s)]+1\)
                    \(\mathrm{R}[\mathrm{H}(\mathrm{s})] \leftarrow \mathrm{i}\)
    for \(j \leftarrow 1\) to \(n-l+1\)
    do for each length- \(l\) sequence \(s\) in \(\mathrm{N}\left(\mathrm{S}_{t}[j \ldots j+l-1], d\right)\)
                do if \(\mathrm{V}[\mathrm{H}(s)]=t\)
                    then insert \(s\) into \(C\)
```

According to the definition of the Planted $(l, d)$-Motif Problem, each input sequence contains a variant of motif $M$. If a length- $l$ sequence does not have any variant in one of the input sequence, it will not be the motif and will not be stored in the hash tables. Therefore the storage space can be reduced from $O\left(n t(3 l)^{d}\right)$ to $O\left(n(3 l)^{d}\right)$. The correctness of the Basic Voting Algorithm is straightforward and thus omitted. Theorem 1 proves that the time and space complexities of the algorithm are $O\left(n t(3 l)^{d}\right)$ and $O\left(n(3 l)^{d}+n t\right)$ respectively. On the other hand, the brute-force algorithm takes $O\left(n t 4^{l}\right)$ time and $O(n t)$ space. Waterman et al. [24] have designed an algorithm for finding consensus in the input sequences based on an idea similar to voting. However, since their method is not designed for solving the Planted $(l, d)$-Motif Problem, it takes $O\left(4^{l}\right)$ time to fill in an entry of the hash table and another $O\left(4^{l}\right)$ time to scanning the hash table for finding the motif. As a result, it has a time complexity of $O\left(4^{l} n t(3 l)^{d}\right)$ instead of $O\left(n t(3 l)^{d}\right)$.

Although the basic Voting Algorithm runs faster than the brute-force algorithm does, the required space grows exponentially with $d$. Thus, the basic Voting algorithm cannot handle long motifs with large Hamming distance $d$. A method to reduce space complexity is to divide the $4^{l}$ length- $l$ sequences into groups and to process each group one by one. We group the $4^{l}$ length $l$ sequences $s$ according to their suffixes of length $l-l$ '. Two length- $l$ sequences are in the same group if and only if their suffixes are the same. Instead of scanning the input sequences once, we scan the input sequences $4^{l-l^{\prime}}$ times for the $4^{l-l^{\prime}}$ groups of sequences. For each iteration, each substring $\sigma$ in the input sequences will be processed and one vote will be given to its variants with a particular suffix. Theorem 2 proves that the time and space complexities of this modified algorithm are $O\left(n t(3 l)^{d}+\right.$
$\left.n t 4^{l-l^{\prime}}\right)$ and $O\left(n\left(3 l^{\prime}\right)^{d}+n t\right)$ respectively. Note that when $l-l^{\prime}$ is $\Omega\left(\log _{4}(3 l)^{d}\right), O\left(n t(3 l)^{d}+\right.$ $\left.n t 4^{l-l^{\prime}}\right)=O\left(n t(3 l)^{d}\right)$.

Theorem 1: The time and space complexities of the basic Voting Algorithm are $O\left(n t(3 l)^{d}\right)$ and $O\left(n(3 l)^{d}+n t\right)$ respectively.
Proof: Let $\mathrm{K}(l, d)$ be the size of $\mathrm{N}(\sigma, d)$ for any length- $l$ substring $\sigma$. Substring $\sigma$ starting at position $j$ in the $i$-th input sequence $s_{i}$ is represented by $\mathrm{S}_{i}[j \ldots j+l-1]$ (line 5 of Algorithm 1) where $\mathrm{S}_{i}[j]$ is the $j$-th character of $\mathrm{S}_{i}$.

$$
\mathrm{K}(l, d)=\sum_{i=0}^{d} \mathrm{C}_{i}^{l} 3^{i}=O\left((3 l)^{d}\right)
$$

where $\mathrm{C}_{i}^{l}$ is the number of ways of choosing $i$ objects from $l$. Since we can access each entry in the hash tables V and R in constant time, the voting on all $d$-variants of a length- $l$ substring $\sigma$ in an input sequence (lines 5 to 8 of Algorithm 1) takes $O(\mathrm{~K}(l, d)$ ) time. Therefore, when all the length $l$ substrings of the $t$ length- $n$ sequences are considered, it will take $O(n t \mathrm{~K}(l, d)$ ) time in total (the two for-loops of $i$ and $j$ in lines 3 to 8 ). Finally we have to check $\mathrm{K}(l, d)$ entries for each of the $n-1+1$ substring $s$ for motif candidates, i.e. those entries which have received $t$ votes (line 9 to 12 of Algorithm 1). This checking will take $O(n \mathrm{~K}(l, d))$ time. Thus the running time of the basic Voting Algorithm is $O(n t \mathrm{~K}(l, d))$ $+O(n \mathrm{~K}(l, d))=O(n t \mathrm{~K}(l, d))=O\left(n t(3 l)^{d}\right)$.

Each length- $l$ substring in the first input sequence has $\mathrm{K}(l, d)$ variants. Therefore, at most $(n-l+1) \mathrm{K}(l, d)$ length- $l$ sequences will get one vote after processing the first input sequence $S_{1}$. Since only those length- $l$ sequences that get a vote when processing $S_{1}$ can possibly be the motif, we need only to keep track of votes for these length-l sequences when processing the remaining sequences $\mathrm{S}_{2} \ldots \mathrm{~S}_{t}$. So, the maximum number of possible candidates for the motif, i.e. size of the two tables V and R in Algorithm 1, is at most ( $n-$ $l+1) \mathrm{K}(l, d)$ or $O\left(n(3 l)^{d}\right)$. As the space needed to store the input sequences is $O(n t)$, the space complexity of the algorithm is $O\left(n(3 l)^{d}+n t\right)$.

Theorem 2: The time and space complexities of the modified Voting Algorithm are $O\left(n t(3 l)^{d}+n t 4^{l-l^{\prime}}\right)$ and $O\left(n\left(3 l^{\prime}\right)^{d}+n t\right)$ respectively.
Proof: Although we have divided the length- $l$ sequences into $4^{l-l}$ groups, the total number of votes remains $O(n t \mathrm{~K}(l, d))$ issued by the length- $l$ substrings. However, since we have to scan the input sequences $4^{l-l^{\prime}}$ times, the modified Voting Algorithm will take $O(n t \mathrm{~K}(l, d)+$ $\left.n t 4^{l-l^{l}}\right)=O\left(n t(3 l)^{d}+n t 4^{l-l^{\prime}}\right)$ time.
At each iteration, we need to store the votes for a group of length- $l$ sequences with a particular length- $(l-l$ ') suffix only, the space needed (i.e. tables V and R in Algorithm 1) decreases from $O(n \mathrm{~K}(l, d))$ to $O\left(n \mathrm{~K}\left(l^{\prime}, d\right)\right.$. Thus, the space complexity of the modified Voting Algorithm is $O\left(n \mathrm{~K}\left(l^{\prime}, d\right)+n t\right)=O\left(n\left(3 l^{\prime}\right)^{d}+n t\right)$.

## 3 Heuristic Improvements

Although the Voting Algorithm can solve the Planted ( $l, d$ )-Motif Problem for many $l$ and $d$ including the challenging $(9,2),(11,3),(15,5)$-motif problems, its running time increases exponentially with $d$ and the length of suffix. Therefore, it cannot handle problem with large $l$ and $d$. In order to handle longer motifs, we introduce two heuristic improvements for the Voting Algorithm.

### 3.1 Random Projection

When $l$ is large, say $l>15$, the time required for finding the motif becomes prohibitively long when $d>5$. We try to reduce the size of $l$ by projecting all length- $l$ substrings onto a subset of these $l$ positions. This subset of positions can be randomly chosen and the size of the subset, say $l$ ', should be small enough to be solvable by the previous Voting Algorithm. A similar projection idea was used by Buhler et al [3] in which each length- $l$ substring in the input sequences gives only one vote to the length-l' projected sequence (thus a total of $t(n-l+1)$ votes will be issued) and those length- $l$ ' substrings with votes larger than some predefined threshold are used as seeds for finding the motif by an EM algorithm. Their algorithm is successful only when a sufficiently large number of $d$ variants of the motif having the same nucleotides at the $l$ ' projected positions. In our algorithm, each length- $l$ substring in the input sequences gives votes to several length-l' substrings instead of one $\left(O\left(3 l^{\prime}\right)^{d l^{\prime} l}\right)$ time more votes than Buhler et al's algorithm). As a result, our algorithm can find the motif even when the number of $d$-variants of the motif having the same nucleotides at the $l$ ' projected positions is small. Besides, our algorithm can find the motif directly instead of further applying a local searching algorithm.

Denote $\mathrm{HD}\left(s, s^{\prime}\right)$ be the Hamming distance between sequences $s$ and $s^{\prime}$. Let $B$ be a subset of $l$ ' positions from $\{1, \ldots, l\}$. A projection $\operatorname{proj}(s, B)$ of a length- $l$ sequence $s$ is the length- $l$ ' sequence constructed by projecting the $l$ ' characters from $s$ at the positions specified by $B$. Our approach is to perform voting on these length-l' projected sequences. For each length- $l$ substring $\sigma$ in the input sequences, one vote will be given to a length- $l$ ' sequence $s$ if $\operatorname{HD}(\operatorname{proj}(\sigma, B), s) \leq\left\lceil d l^{\prime} / l\right\rceil$. In general, for a length- $l$ variant $m_{i}$ of $M$, i.e. $\operatorname{HD}\left(m_{i}, M\right) \leq d$, it is expected that the length- $l$ ' sequence $\operatorname{proj}\left(m_{i}, B\right)$ is also a $\left\lceil d l^{\prime} / l\right\rceil$ variant of $\operatorname{proj}(M, B)$, i.e. $\left.\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq\left\lceil d l^{\prime} /\right\rceil\right\rceil$, and $\operatorname{proj}(M, B)$ will be voted. However, even if $M$ has $t$ variants $\left\{m_{i}\right\}, \operatorname{proj}(M, B)$ may not get exactly $t$ votes in the following cases:
(i) $\operatorname{proj}(M, B)$ is not voted by some planted variant $m_{i}$ because $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right)>\left\lceil d l^{\prime} / l\right\rceil$.
(ii) $\operatorname{proj}(M, B)$ is voted by a substring $\sigma$ even though $\operatorname{HD}(\sigma, M)>d$ because $\operatorname{HD}(\operatorname{proj}(\sigma, B), \operatorname{proj}(M, B)) \leq\left\lceil d l^{\prime} / l\right\rceil$.
We shall show later that when $l^{\prime}$ is comparatively large with respect to $l$, say $l^{\prime} \approx 2 l / 3$, it is highly probable that $\operatorname{proj}(M, B)$ will receive votes from the plant variants $m_{i}$ of motif $M$.

Theorem 3: Given a random set $B$ of size $l^{\prime}$ and $t$ length- $l$ planted variants of a motif $M$ with at most $d$ substitutions, the probability $\mathrm{P}_{\mathrm{r}}(l, l,, d, t, t)$ that "at least $t$ ' out of the $t$ variants give vote to $\operatorname{proj}(M, B)$ after performed projection according to $B$ " is at least

$$
\sum_{i=l^{\prime}}^{t} \mathrm{C}_{i}^{t} p\left(l, l^{\prime}, d\right)^{i}\left(1-p\left(l, l^{\prime}, d\right)^{i}\right)^{t-i} \text { where } p\left(l, l^{\prime}, d\right)=\sum_{i=0}^{\left.\left\lceil d l^{\prime} l\right\rceil\right\rceil} \frac{\mathrm{C}_{i}^{d} \cdot \mathrm{C}_{l^{\prime}-d}^{l-d}}{\mathrm{C}_{l^{\prime}}^{l}}
$$

Proof: Let $p\left(l, l^{\prime}, d\right)$ be the probability that $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq\left\lceil d l^{\prime} / l\right\rceil$ for a variant $m_{i}$ of $M$ with exactly $d$ substitutions. Since there are $\mathrm{C}_{i}^{d} \cdot \mathrm{C}_{l^{\prime}-i}^{l-d}$ out of $\mathrm{C}_{l}^{l}$ possible $B$ such that $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right)=i, p\left(l, l^{\prime}, d\right)=\sum_{i=0}^{\left[d l^{\prime \prime}\right]} \mathrm{C}_{i}^{d} \cdot \mathrm{C}_{l-i}^{l-d} / \mathrm{C}_{l^{l}}^{l}$.
$\mathrm{P}_{\mathrm{r}}\left(l, l^{\prime}, d, t, t^{\prime}\right)$ has the minimum value when $\mathrm{HD}\left(m_{i}, M\right)=d$ for all variants $m_{i}$, which is equal to $\sum_{i=t^{\prime}}^{t} \mathrm{C}_{i}^{t} p\left(l, l^{\prime}, d\right)^{i}\left(1-p\left(l, l^{\prime}, d\right)^{i}\right)^{t-i}$ using binomial distribution, Therefore $\mathrm{P}_{\mathrm{r}}\left(l, l^{\prime}, d, t, t^{\prime}\right)$ is at least $\sum_{i=l^{\prime}}^{t} \mathbf{C}_{i}^{t} p\left(l, l^{\prime}, d\right)^{i}\left(1-p\left(l, l^{\prime}, d\right)^{i}\right)^{t-i}$.

Let $\left\{v_{i}\right\}$ be the set of length- $l$ substrings which vote $\operatorname{proj}(M, B)$. Although $\left\{m_{i}\right\}$ and $\left\{v_{i}\right\}$ may be different because of the above cases, large proportion of substrings $\left\{m_{i}\right\}$, say $t$ ' length- $l$ variants of $M$, are in $\left\{v_{i}\right\}$ and $t^{\prime}$ should be slightly less than $t$. Thus, $\operatorname{proj}(M, B)$ will receive high votes and will be used to identify $\left\{v_{i}\right\}$ in the input sequences. The last procedure is to finding the motif from this set of length- $l$ substrings. We choose to find the motif using clique search method. In practice, the running time for finding the maximum clique is acceptable [4] as the size of the graph is usually very small.

Table 1 shows the value of $\mathrm{P}_{\mathrm{r}}\left(l, l^{\prime}, d, t, t^{\prime}\right)$ for different values of $l, d$ and $t^{\prime}$ when $t=20$ and $l^{\prime} \approx 2 l / 3$, e.g., the probability that there are at least 14 variants of $M$ in the variants set of $\operatorname{proj}(M, B)$ is larger than 0.4165 (when $l=30, d=12$ ) which is much larger than the probability for a set of randomly-generated sequences. Although this probability $\mathrm{P}_{\mathrm{r}}\left(l, l^{\prime}, d, t, t^{\prime}\right)$ might not be large enough to guarantee the finding of $M$, we can repeat the process with different sets of positions $B$ to increase the probability of finding $M$. With respect to the above example, if we repeat this process 10 times for $t=20$, the probability that 14 or more variants of motif $M$ are in $\left\{v_{i}\right\}$ will increase to $1-(1-0.4165)^{10}=0.9954$.

Table 1: $\mathrm{P}_{\mathrm{r}}\left(l, l^{\prime}, d, t, t t^{\prime}\right)$ for different $l, d$ and $t^{\prime}$ when $t=20$ and $l^{\prime}=2 l / 3$

### 3.2 Improved Random Projection

Although we have high probability to find the motif using Random Projection, we can further increase this probability by considering the complement of the set $B$ of positions.

Consider a set $B$ of $\lfloor l / 2\rfloor$ positions, define $B^{c}$ be the complement of $B$, i.e. $B^{c}=$ $\{1, \ldots, l\}-B$. If $m_{i}$ is a length- $l$ planted variant of the motif $M$, then either $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq\lfloor d / 2\rfloor$ or $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B^{c}\right), \operatorname{proj}\left(M, B^{c}\right)\right) \leq\lceil d / 2\rceil$. Let $\left\{v_{i}\right\}$ and $\left\{v_{i}^{c}\right\}$ be the set of length- $l$ variants obtained $\operatorname{from} \operatorname{proj}(M, B)$ and $\operatorname{proj}\left(M, B^{c}\right)$ respectively. At least half of the variants of motif $M$ should be in $\left\{v_{i}\right\}$ or $\left\{v_{i}^{c}\right\}$. Calculation of the probability $\mathrm{P}_{\mathrm{h}}\left(l, d, t, t^{\prime}\right)$ that at least $t^{\prime}$ of the $t$ variants of a length- $l$ motif $M$ are in $\left\{v_{i}\right\}$ or in $\left\{v_{i}^{c}\right\}$ is shown in Theorem 4.

Theorem 4: Given a random set $B$ of size $l / 2$ and $t$ length- $l$ planted variants of a motif $M$ with at most $d$ substitutions, the probability $\mathrm{P}_{\mathrm{h}}\left(l, d, t, t^{\prime}\right)$ that either $\operatorname{proj}(M, B)$ or $\operatorname{proj}\left(M, B^{c}\right)$ gets at least $t^{\prime}$ votes from the $t$ variants when performing random projection is at least

$$
\sum_{j=0}^{t}\left[\left(\mathrm{C}_{j}^{t} p_{e}^{j}\left(1-p_{e}\right)^{t-j}\right) \bullet\left(\sum_{k=\left\{0, \ldots, t-t, t^{\prime}-j, \ldots, t-j\right\}} \mathrm{C}_{k}^{t-j}\left(\frac{1}{2}\right)^{t-j}\right)\right] \text { where } p_{e}=\frac{\mathrm{C}_{d / 2}^{d} \bullet \mathrm{C}_{(l-d) / 2}^{(l-d)}}{\mathrm{C}_{l / 2}^{l}}
$$

Proof: Assume both $l$ and $d$ are even. Let $p_{e}$ be the probability that a variant $m_{i}$ of $M$ with exactly $d$ substitutions gives vote to both $\operatorname{proj}(M, B)$ and $\operatorname{proj}\left(M, B^{c}\right)$. It would happen only when $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right)=\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B^{c}\right), \operatorname{proj}\left(M, B^{c}\right)\right)=d / 2$. It means that set $B$ contains exactly $(l-d) / 2$ positions that $m_{i}$ equals $M$. Since there are $\mathrm{C}_{d / 2}^{d} \bullet \mathrm{C}_{(l-d) / 2}^{l-d}$ out of $\mathrm{C}_{l / 2}^{l}$ possible $B$ satisfying this requirement, $p_{e}=\mathrm{C}_{d / 2}^{d} \bullet \mathrm{C}_{(l-d) / 2}^{(l-d)} / \mathrm{C}_{l / 2}^{l}$.
$\mathrm{P}_{\mathrm{h}}\left(l, d, t, t^{\prime}\right)$
$\geq$ The probability that there are $t$ ' or more variants $m_{i}$ satisfying $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq d / 2$ or there are $t^{\prime}$ or more variants $m_{i}$ satisfy $\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B^{c}\right), \operatorname{proj}\left(M, B^{c}\right)\right) \leq d / 2$ given tha $\mathrm{HD}\left(m_{i}, M\right)=d$ for all variants $m_{i}$
$=\sum_{j=0}^{t} \mathrm{P}\left(\exists j\right.$ variants $\left.m_{i} \operatorname{s.t.} \operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right)=\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B^{c}\right), \operatorname{proj}\left(M, B^{c}\right)\right)=d / 2\right)$
$\bullet \mathrm{P}\left(\exists t^{\prime}-j\right.$ or more variants $m_{i}$ in the rest $t-j$ variants s.t. $\mathrm{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq d / 2$ or $\exists t-t^{\prime}$ or less variants $m_{i}$ in the rest $t-j$ variants s.t. $\left.\operatorname{HD}\left(\operatorname{proj}\left(m_{i}, B\right), \operatorname{proj}(M, B)\right) \leq d / 2\right)$
$=\sum_{j=0}^{t}\left[\left(\mathrm{C}_{j}^{t} p_{e}{ }^{j}\left(1-p_{e}\right)^{t-j}\right) \cdot\left(\sum_{k=\left\{0, \ldots, t^{\prime} t^{\prime},-j, \ldots, t-j\right)} \mathrm{C}_{k}^{t-j}\left(\frac{1}{2}\right)^{k}\left(\frac{1}{2}\right)^{t-j-k}\right)\right]$
$=\sum_{j=0}^{t}\left[\left(\mathrm{C}_{j}^{t} p_{e}^{j}\left(1-p_{e}\right)^{t-j}\right) \bullet\left(\sum_{k=\left\{0, \ldots, t t^{t}, t^{t}-j, \ldots, t-j\right\}} \mathrm{C}_{k}^{t-j}\left(\frac{1}{2}\right)^{t-j}\right)\right]$

The values of $\mathrm{P}_{\mathrm{h}}\left(l, d, t, t^{\prime}\right)$ for different $l, d$ and $t^{\prime}$ when $t=20$ are shown in Table 2. Although the probability $\mathrm{P}_{\mathrm{h}}(l, d, t, t$ ') decreases with $l$, the probability "at least 14 of the 20 variants of motif $M$ are in $\left\{v_{i}\right\}$ derived from $\operatorname{proj}(M, B)$ or in set $\left\{v_{i}^{c}\right\}$ derived from
$\operatorname{proj}\left(M, B^{c}\right)^{\prime \prime}$ is larger than 0.7433 (an increase from 0.4165 of the random projection method). Note that $\mathrm{P}_{\mathrm{h}}\left(l, d, t, t^{\prime}\right)=1$ for all $t^{\prime} \leq t / 2$, therefore at least $t / 2$ variants $\left\{m_{i}\right\}$ are in $\left\{v_{i}\right\}$ or $\left\{v_{i}^{c}\right\}$. Similar to the Random Projection, we can take different random sets $B$ so as to increase this probability. For example, if we repeat the process 5 times, the probability of at least 14 out of 20 variants in $\left\{v_{i}\right\}$ or $\left\{v_{i}^{c}\right\}$ will be $1-(1-0.7433)^{5}=0.9989$.

When using this improved Random Projection approach, we should be careful that the motif must be long. If the length of the motif is short, say 16 bp , the length of the short motif ( 8 bp ) is too short that there will be many random sequences having a lot of variants. The running time of the Voting Algorithm will increase, as we have to find the length- $l$ variants for a huge number of short motifs in order to find the corresponding candidate motif.

On the other hand, if the length of the motif is sufficient long, say 40 , the improved Random Projection Algorithm should be applied to reduce to a motif problem of length 20, which can further be solved by the Random Projection Algorithm.

## 4 Experimental results

In this section, we describe the test results of the Voting Algorithm for both simulated and real biological data. The experiments were taken on a 2.4 GHz CPU with 512 MB memory.

### 4.1 Simulated Data

We tested the performances of brute-force algorithm, Voting Algorithm and Voting Algorithm with heuristic improvement on different Planted (l,d)-Motif Problem. Table 3 shows the suggested heuristic improvement with respect to different $l$ and $d$.

Table 3: Suggested heuristic improvement used in different situations " $S$ " means using the Voting Algorithm without heuristic improvement. "RP" means using the random projection with $l$ ' $=2 l / 3$. "RPH" means using the random projection with the complement set $\left(l^{\prime}=l / 2\right)$

|  | $l<\mathbf{1 5}$ | $\mathbf{1 5} \leq l \leq \mathbf{2 0}$ | $\mathbf{2 0}<\boldsymbol{l}$ |
| :---: | :---: | :---: | :---: |
| $\boldsymbol{d} \leq \mathbf{3}$ | S | S | S |
| $\mathbf{3} \boldsymbol{d} \leq 5$ | S | S | RPH |
| $d>5$ | S | RP | RPH |

All input instances contain $t=20$ sequences, each of length 600. Each nucleotide (' $A$ ', ' $C$ ', ' $G$ ' and ' $T$ ') of the input sequences was generated independently with the same occurrence probability. A motif $M$ of length- $l$ was randomly picked and a variant was planted to each input sequence. Each algorithm could output at most 20 candidates for possible solutions (the length- $l$ sequences with at least one variant in each input sequence). The pattern with the minimum Hamming distance with the planted motif will be considered as the solution of the algorithm. For each set of parameter $l$ and $d$, we ran 50 test cases and recorded the average running time of each algorithm along with the average Hamming distance between the solution and the planted motif.

Table 4 shows the results of the experiments. The third column is the maximum value of $d$ for the corresponding $l$ such that the Planted ( $l, d$ )-Motif Problem can still be solved theoretically. Buhler et al [3] introduced the expected number $\mathrm{E}(l, d)$ of length- $l$ random sequences that have one variant in each input sequence. When $\mathrm{E}(l, d)$ is large, no algorithm can determine the motif from the set of random sequences with a variant in each input sequence. In other words, $\max \{d \mid \mathrm{E}(l, d)<$ some threshold $\}$ gives the maximum $d$ that the $(l, d)$-motif problem can be solved.

Since the brute-force algorithm takes $O\left(n t 4^{l}\right)$ time, the running time for finding a length-11 motif is over 4.8 h and it cannot handle longer motif in reasonable time. Although Voting Algorithm can solve the Planted ( $l, d$ )-Motif Problem for longer motif than the brute-force algorithm can, it cannot handle those problem when $d$ is larger than 5 as its running time increases exponentially with $d$. With heuristic improvement, the Voting Algorithm can handle longer motif with large $d$ even for the (40,15)-motif problem in one minute.

Table 4: Experimental results on simulated data of the brute-force algorithm, Voting Algorithm and Voting Algorithm with heuristic improvement We run 50 test cases for each set of parameters and recorded the average running time and the hamming distance between the planted motif and the solution output by the three programs. "-" means that the running time of the program is too long (at least more than one day).

### 4.2 Real Biological Data

SCPD [26] contains different transcription factors for yeast. For each set of genes regulated by the same transcription factor, we chose the 600 bp in the upstream of the genes as the input sequences $T$. The lengths of the motifs were same as those of the published motifs and $d$ was 1 or 2 . We have compared the performance of the Voting algorithms with a common motif discovery algorithm called MEME [1]. Experimental results are shown in Table 5. MEME [1] uses a $4 \times l$ probability matrix to represent the motif. Although matrix representation $[1,5,6,13]$ can model a motif better than using a string, the Voting algorithm outperformed MEME in some cases because no algorithm can guarantee finding a motif in matrix representation in reasonable time especially when the motif is long. On the other hand, the Voting Algorithm can find the motif quickly (the running time of the Voting Algorithm was within one second for each data set) if the motif can be represented by a string.

## 5 Extension

Some genes cannot be regulated by a single transcription factor. A gene may express only when several types of transcription factors are bound to a set of binding sites in the promoter region of the gene. These binding sites are organized into short sequence units called cis-regulatory modules (CRM). A CRM cannot be represented by a single motif but by a set of motifs $M_{i}$. The Planted CRM Problem which has been considered in [17,21] is defined as follows.

Planted CRM Problem: Suppose there is a CRM represented by $K$ motifs. The length of each motif $M_{i}$ is $l_{i}$. Each input sequence contains a planted $d_{i}$ variant of each motif $M_{i}$ where the $d_{i+1}$-variant of $M_{i+1}$ occurs no less than $\min _{i}$ and no more than $\max _{i}$ nucleotides after the end of the $d_{i}$-variant of $M_{i}$. Given $t$ length- $n$ input sequences, we want to determine the $K$ motifs $M_{i}$ without knowing the positions of the planted variants.

The Voting Algorithm can solve this problem with some modifications. We concatenate on the planted CPM problem with $K$ motifs, represented by a length- $\sum_{i=1}^{K} l_{i}$ sequence. Instead of constructing the hash tables V and R for $4^{l}$ possible length- $l$ candidate motifs, we construct the hash tables for $4^{\Sigma l_{i}}$ possible length- $\sum_{i=1}^{K} l_{i}$ sequences. For each substring $\sigma$ of length in the range $\left[\sum_{i=1}^{K} l_{i}+\sum_{i=1}^{K-1} \min _{i}, \sum_{i=1}^{K} l_{i}+\sum_{i=1}^{K-1} \max _{i}\right.$ ], we give one vote to those length $-\sum_{i=1}^{K} l_{i}$ sequences that have variants in $\sigma$. The length- $\sum_{i=1}^{K} l_{i}$ sequence with exactly $t$ marks represents the set of motifs.

From my best knowledge, RISO [21] is the fastest algorithm and it takes about 17000 seconds on a 2.4 GHz CPU to solve the planted CRM problem when $l_{1}=l_{2}=7, d_{1}=2, d_{2}$ $=1, \min _{1}=\max _{1}=15$ and $n=t=2000$ (Please refer [21] for more details). We repeated the same experiment by the Voting Algorithm and found the correct motifs in only 7400
seconds. Besides, all motifs found by RISO on real data set from TRANSFAC (http://www.gene-regulation.com) can be found by the Voting Algorithm.

## 6 Discussion

In this paper, we have introduced the Voting Algorithm for solving the Planted ( $l, d$ )-Motif Problem. It guarantees that the motif can be found when $d$ is small and with high probability for large $l$ and $d$. Experimental results have indicated that our algorithm works quite well for both simulated data and real data.

Since some binding sites have slightly different length, an open problem of interest is to extend the Voting Algorithm to handle those variants within $d$ from motif $M$ in edit distance instead of Hamming distance. Besides substitution, edit distance allows insertion and deletion which can model binding sites with different lengths. When $d$ is small, this problem can be solved by redefining the variant set $N(\sigma, d)$ of a length- $l$ substring $\sigma$. However, the heuristic improvement may not work when both $l$ and $d$ are large and new methods should be needed to handle these cases. Another problem is considering a set of sequences with no binding site as an additional input [7]. With this additional set, we may find motif even when the Hamming distance $d$ is large than the threshold, e.g. $(9,3)$, $(11,4),(15,6)$-motif problem.
